9 **A novel multiplex-PCR assay to detect three non-halal meats contained in meatball**
10 **using mitochondrial 12S rRNA gene**

11
12 **Abstract**

13 The objective of this study was to detect three non-halal meat products consisted of dog,
14 pork, and rat species in meatball using novel multiplex-PCR with 12S rRNA gene as target
15 sites. A total of 33 self-made meatballs were used, and they were grouped into eleven types of
16 meatball based on meat species origin contained in the meatballs. Each type consisted of three
17 meatballs. Extraction of genomic DNA from the meatballs was used as a DNA template for
18 simplex-, duplex-, and multiplex-PCR processes. The result of simplex-PCR, duplex-PCR,
19 and multiplex-PCR showed that the 12S rRNA primer gene successfully amplified DNA for
20 each species bovine, dog, pig, and rat, which are respectively indicated by 155, 244, 357, and
21 491 bp of DNA bands. In addition, multiplex-PCR with 12S rRNA gene primers can be
22 uniquely and accurately used for detection bovine, dog, pig, and rat species on beef meatball
23 in one reaction.

24 **Keywords:** meatball, multiplex-PCR, non-halal, species, 12S rRNA

25
26 **Introduction**

27 Beef is one of the most popular livestock commodities in Indonesia, which is consumed as
28 meat and processed products such as meatball. Increasing beef demand as a main ingredient
29 of meatballs, which is not balanced with sufficient supply of beef, creates an opportunity to
30 adulterate and mix beef with other meat sources. Consumers find it difficult to prove which
31 original beef or adulterated beef by bare eyes; it is even more challenging to identify beef
32 adulteration in processed products. Adulteration of raw beef with other meats and its

33 processed products can cause various problems, including consumer satisfaction, social
34 problems, particular religious preferences, and other problems related to health hazards
35 associated with certain types of substances from certain types of meat (Kumar et al., 2014).

36 Cases of beef adulteration are not only limited to substitution with pork (Ha et al., 2017). In
37 Indonesia, beef adulteration is also mixed with dog and rat meats due to both types of meat is
38 served as food in some cities (Weichart, 2004). The level of dog meat consumption in Asia,
39 especially in Indonesia, is reasonably high because of eating dog meat is culturally permitted
40 behavior in several Indonesian regions. It is reported that around one thousand dogs are
41 slaughtered and served as food every week (Weichart, 2004; Podsberscek, 2009). In the
42 Europe, the idea of consuming dog meat is seen as something disgusting because, generally,
43 dogs are kept as pets (Podsberscek, 2009). Meat from dog, pig, and rat species has been
44 regulated by criteria for prohibited consumption in Islamic law (Fadzlillah et al., 2011). In
45 addition, these types of animals also have the potential to become zoonotic agents (Fajardo et
46 al., 2010; Hamidi, 2018). If this type of meat is used in multi-species adulteration, it will be
47 harmful not only for Moslem but also for all consumers.

48 Labeling regulation requires that compositions of meat products must be clearly stated in
49 the package to protect the worldwide consumer from deviant meat products (Doosti et al.,
50 2014; Abuzinadah et al., 2015). Stating composition in the package is obviously intended to
51 protect consumers from fraud and adulteration. Sometimes producers of beef product do not
52 provide clear information in the package, and they are often deliberately mixed beef with pork
53 and its derivatives due to the obvious economic benefits in some countries like Korea, Japan,
54 and China where beef is much expensive than pork (Ha et al., 2017).

55 The DNA-based method much more effective than using physical properties of meat in
56 determining of meat species origin (Tathma et al., 2019). The application of this method for
57 identification species origin contained in meat products using polymerase chain reaction

58 (PCR) technique is frequently applied because DNA is quite stable against high temperature,
59 pressure, and chemical treatments (Fajardo et al., 2010; Saez et al., 2004). The multiplex-PCR
60 method uses more than one primer in one PCR tube. Therefore, it can be used to analyze large
61 sample quantities, saving time, cost, and it is also highly sensitive (Dalmaso et al., 2004).
62 Most of the previous studies develop mitochondrial genome such as Cytochrome b and 12S
63 rRNA genes as target sites for phylogenetic, evolution, and species identification studies due
64 to their unique nucleotides and maternally inherited to the offspring. The 12S rRNA region
65 has been used for species identification in raw meats using multiplex PCR assay (Cahyadi et
66 al., 2018; Cahyadi et al., 2019). Therefore, the objective of this study was to detect
67 intentionally contaminated beef meatball with three non-halal meats (dog, pork, and rat) using
68 multiplex PCR with the 12S rRNA region designed as target sites.

69

70 Materials and Methods

71 Meat samples

72 The samples of beef and pork were collected from traditional markets in Surakarta City.
73 Dog and rat meats were collected from meat sellers who are not willing to be published to the
74 public. Each meat sample was put into a zip locked plastic bag and tagged with a specific
75 name and stored separately to avoid cross-contamination among samples until used for further
76 process in the refrigerator at 4°C.

77

78 Producing of self-made meatball

79 Meats were thawed and cut into small pieces using sharp knives. They were ground using
80 different meat grinder for each meat species (Huamei Meat Mincer LH-22CW). Ground meats
81 were gently mixed with wheat flour, garlic powder, salt, and pepper until homogeneous.

82 Ingredient of each sample unit is presented in Table 1. Furthermore, meatball doughs were
83 shaped like a ball by hand, and then they were boiled for 20 minutes until floating. Cooked
84 meatballs were drained and left at room temperature. Finally, they were separately stored in
85 the freezer at -20°C until used for the subsequent analysis. The process of making meatball in
86 this study used different equipment for each sample unit to prevent cross-contamination
87 among samples (Sari et al., 2017).

88 Meatball samples in this study were divided into eleven sample units (Table 1). Every unit
89 has three replications. Samples of S, A, B, and T meatballs were set for simplex PCR, duplex-
90 (SA, SB, and ST), and multiplex-PCR (SAB, SAT, SBT, and SABT) were made based on a
91 combination of the composition of meat from beef (S), dog (A), pork (B), and rat (T). Those
92 samples were used to test the uniqueness and specificity of the 12S rRNA gene primers using
93 genomic DNA templates extracted from meatballs.

94 95 Isolation of Genomic DNA

96 The **genomic DNA** was extracted according to the procedure of gsync™ DNA extraction
97 kit for tissue (Geneaid Biotech Ltd., Taiwan). The isolated genomic DNA was stored at -20°C
98 until used for PCR (Yacoub & Sadek, 2016). To evaluate the quality of isolated genomic DNA,
99 1% agarose gel electrophoresis was performed at 100 Volts for 30 minutes. Moreover, stained
100 agarose gel was put into gel document to capture photograph (Bio-Rad Gel Doc™ XR +,
101 United State of America).

102

103 Polymerase chain reaction (PCR)

104 The genomic DNA extracted from the meatball sample was used as a DNA template for the
105 purpose of obtaining specific segments of the 12S rRNA gene as target using primers
106 previously reported by Cahyadi et al. (2018) and Cahyadi et al. (2019). Primer pairs are

107 shown in Table 2. Simplex-, duplex-, and multiplex-PCR reactions were carried out using a
108 thermal cycler machine (GeneAmp® PCR System 9700, Singapore). The total volume of
109 reaction in the microtube was 25 μ L consisting of 12.5 μ L MyTaq™ HS Red Mix (Bioline,
110 UK), 1 μ L genomic DNA template (10 ng/ μ L), 1 μ L forward primer, 1 μ L each reverse primer,
111 and ddH₂O adjusted until reach 25 μ L total volume. Simplex PCR only contained one primer
112 pair, duplex PCR contained two primer pairs (bovine primers and another species primers),
113 and multiplex PCR contained all primer pairs. The concentration of each primer in the
114 reaction was 10 μ M. The PCR reaction was started with an initial denaturation at 95°C for 3
115 minutes and followed by 30 cycles of denaturation at 95°C for 15 seconds, annealing at 64°C
116 for 30 seconds, and then extension at 72°C for 30 seconds. The PCR process was completed
117 by final extension at 72°C for 3 minutes. Finally, PCR products were electrophoresed using
118 2% agarose gel at 100 Volts for 30 minutes. Electrophoresis results were visualized using a
119 gel document machine (Bio-Rad Gel Doc™ XR +, United State of America). The 100 bp
120 marker ladder was used as a standard size of the DNA band.

121

122 Results

123 Simplex PCR

124 Simplex PCR was conducted using meatball samples containing one species of meat origin.
125 The result showed that primer pairs specifically for bovine, dog, pig, and rat correctly
126 amplified target sites. Physical and heat treatment of samples during meatball-making did not
127 affect DNA amplification. Simplex-PCR was successfully performed which is indicated by
128 155, 244, 357, and 491 bp DNA bands for bovine, dog, pig, and rat, respectively (Fig. 1). The
129 simplex PCR products were also evident. It indicated that DNA extracted in this study was
130 pure, and no other DNA sources originated from other ingredients or RNA contamination.

131 Therefore, every component in the reaction can be simultaneously working to produce
132 specific and clear DNA bands.

133

134 Duplex PCR

135 The aim of duplex PCR was to check the possibility of non-halal meats contaminating beef.
136 The beef was intentionally contaminated with pork, dog, and rat meats that represented non-
137 halal meats. The result showed that duplex PCR was also successfully carried out. Two DNA
138 bands can be noticed corresponding to bovine and dog/porcine/rat specific segments (Fig. 1).
139 The DNA bands were also clear and bright. These results suggested that two DNA genomics
140 successfully extracted from treated meats with excellent purity and concentration of DNA
141 genomes.

142

143 Multiplex PCR

144 Triplex- and tetraplex PCRs represented multiplex PCR. In these tests, beef samples were
145 mixed all together with other meats. The existence of three DNA bands indicated the triplex
146 PCR. Also, the tetraplex PCR was indicated by four DNA bands identified in the agarose gel.
147 The results of multiplex PCR using the 12S rRNA gene as target sites indicated that this novel
148 multiplex PCR was powerful enough to identify non-halal meats in meatballs. The DNA
149 bands can be seen in the samples containing multi DNA sources, except the SAT sample (Fig.
150 1). The DNA band for the rat in the SAT mixture was slight, and it was not as bright as other
151 bands. It may be due to the low concentration of rat genomic DNA extracted from the SAT
152 sample; however, it still can be seen by the bare eyes. To prove specificity of primers,
153 multiple alignment analysis of the 12S rRNA gene sequences obtained from genbank is
154 provided in the Supplementary Fig. 1.

155

156 Discussion

157 The DNA bands of each species in the simplex-, duplex-, and multiplex PCR were
158 explicitly detected. The primer pairs accurately amplified target sites of the 12S rRNA gene.
159 Heat and physical treatment of meats did not affect the PCR results. The reactions were
160 working well, which are indicated by specific and unique DNA bands for each species. The
161 previous study reported that high processing temperatures up to 160°C did not affect the
162 stability of the mitochondrial DNA 12S rRNA gene. It still can be a target of amplification in
163 the PCR (Lakzadeh et al., 2013). The primer pairs of the 12S rRNA gene used in the present
164 study can amplify the target area of the 12S rRNA gene using genomic DNA extracted from
165 meatball samples. This result was in agreement with previous studies that successfully
166 detected non-halal meats in raw meats (Cahyadi et al., 2018; Cahyadi et al., 2019).

167 Detection of a mixture of beef, dog, pig, and rat in raw meat and processed products such
168 as meatballs has also been developed previously using the Cyt b gene (Primasari, 2011;
169 Rahman et al, 2014; Novianty et al., 2016). The 12S rRNA gene primer in the present study
170 has advantages, namely using universal forward primers and specific reverse primers to
171 produce specific results. The primary 12S rRNA gene also has the same annealing
172 temperature, so the multiplex PCR, which is using more than one primer pairs in one tube
173 reaction, generates more accurate amplification targets (Cahyadi et al, 2019). The PCR
174 product size for each species was consistent in the simplex-, duplex-, and also multiplex-PCR.
175 In the SAT meatball, the DNA band of rat species was less bright than other samples
176 containing rat meat. It may be due to a low concentration of extracted rat DNA genomic. Also,
177 the DNA concentration obtained from mix samples cannot be equal even though the meat
178 proportion in the SAT samples was identical. Every part of the meatball cannot be extracted
179 entirely since the reaction during the DNA extraction process cannot be adequately controlled
180 by hand. Degradation of DNA molecules due to heat and physical treatments during

181 processing may also lead to generating low DNA concentration and amplicon of PCR (Di
182 Pinto et al., 2007). The less bright DNA band of multiplex-PCR samples may also be due to
183 unspecific and interference among primers. However, the primer designed in this study was
184 carefully checked by multiple alignment analysis of 12S rRNA gene sequences. The results
185 suggested that reverse primers were specific for each species. It was proved by no identical
186 nucleotide(s) at the three-prime end (3'-end) found in reverse primers. This criterion is
187 absolutely necessary since different nucleotide(s) at the 3'-end of the primer is required for
188 successful multiplex-PCR (Matsunaga et al., 1999).

189 Utilization of the 12S rRNA gene for species identification is previously reported that it
190 can identify species of origin in the feedstuffs up to 0.01% of the DNA genome containing in
191 the sample (Safdar & Junejo, 2015). In terms of using meatballs, earlier reports explained that
192 duplex PCR could detect up to only 1% chicken and pork contamination in the meatball made
193 from beef (Novianty et al., 2016; Sari et al., 2017).

194 This study developed the mitochondrial DNA 12S rRNA gene as a biomarker for non-halal
195 meats detection in processed meat product. This study also focused on identifying more than
196 one species prohibited to be eaten by Muslim using the 12S rRNA gene by developing a
197 multiplex PCR technique. There is no report yet regarded using the Multiplex PCR 12S rRNA
198 gene to identify species in the animal-based product. Therefore, it could be a handy tool to be
199 applied in the vast areas of the food industry. The multiplex PCR can simultaneously amplify
200 several different DNA sequences and gain more information in a single reaction, which leads
201 to more effective and efficient using conventional PCR. On the other hand, the development
202 of other PCRs such as PCR, PCR-RAPD, PCR-RFLP, species-specific PCR, and real-time
203 PCR to detect species in food products are considered to be less efficient because they require
204 the latest technology and high operational costs than multiplex PCR (Fajardo et al., 2010).
205 The main motive for most beef adulteration cases revealed in Indonesia is by mixing beef

206 with large quantities of other animal meats to reduce production costs and to get more
207 financial benefits (Ha et al., 2017). The enactment of Law No. 33 of 2014 concerning
208 Guaranteed halal products in Indonesia makes the method of detecting non-halal ingredients
209 in meat-based foods essential.

210 This novel multiplex PCR with the 12S rRNA gene as a target for amplification could be
211 promising tools to detect existences of porcine, rat, and dog in meat products in supporting
212 Indonesian government policy. This novel finding could be an alternative DNA-based testing
213 method to identify non-halal meats and their derivative materials in foods.

296
297 **Supplementary Fig 1. Multiple alignment of mt-DNA 12S rRNA gene sequences using reference sequences.** Accession numbers of the
298 reference sequences for bovine, dog, porcine, and rat were HQ184045.1, KF907307.1, JN601075.1, and AY769440.1, respectively. Forward
299 primer (F) and complementary sequences of species-specific reverse primers are indicated by black boxes. Dots and grey boxes indicate identical
300 and different nucleotides to the primer sequences, respectively.
